ginners

eady have a repository that you want to

have one.

GitHub access permissions confirmation.

cories from GitHub, go to your profile
`s-broken-example` repository.

s you have admin access to.

vhat to do:

d to test `Test.php` with phpunit against

the empty file. Add the file to git, commit

Migrating to Container-Based Infrastructure

Note: Travis only runs a build on the commits you push after adding the repository to Travis.

Wait for Travis CI to run a build on your fork of the `travis-broken-example` repository, check the build status and notice that the build fails. (Travis CI sends you an email when this happens)

6. Fix the code by making sure that `2=1+1` in `Test.php`, commit and push to GitHub. This time, the build does not fail.

```
$ git add -A
$ git commit -m 'Testing Travis CI: fixing the build'
$ git push
```

Congratulations, you have added a GitHub repository to Travis and learnt the basics of configuring builds and testing code.

Note there is no need to make a pull request to the original repository, the build is run on your fork.
